Stanford ENGINEERING

## I. Task Definition

- Our project explores building generative models for music
- Specifically, the symbolic representation of melodies/notes as in MIDI files
- Our problem consists of:
  - Modelling sequences with language-modelling approaches
  - Inferring (sampling) from our models to generate a melody stream
- Goal: Generate music pleasing to the ear

## II. Dataset

- We used the Reddit MIDI dataset (with over 100,000 different tracks)
- MIDI files contain different 'tracks' for each instrument, aside from the main melody
- Tracks might have multiple notes (chords) playing at once, or silences
- To avoid these issues and work with clearly separated melodies, we used the classical music datasets above (~500 tracks each)

## III. Baseline

- **Baseline:** Generate notes at random, samples according to Pink Noise [p(s) ~ 1/f]
- **Simple Model - Markov Chain:**
  - State: (pitch, duration) - 128x16 total
  - Model  $p(S_i | S_{i-1})$ , via monte carlo estimates of transition probabilities
  - Sample from p during generation
  - Heuristic-based evaluation shows a slightly improvement over baseline
  - Order > 2 infeasible with exponential state blowup - sparse p estimates

## IV. Approach & Experiments

### Model 1 - CharRNN based

(Monophonic - LSTM Cell - state size: 64, input length: 4)

- Models monophonic melodies, can generate qualitatively pleasing notes
- Evaluation heuristics significantly better

### Model 2 - ChordRNN (in progress)

(Polyphonic - LSTM Cell - state size: 32, input length: 16)

- Read in a chord played at every time step for the previous 16 time steps
- Predict the chord to be played in the next time step
- Can encode and understand silence
- Can account for a variable number of notes played at every time step

### Note-Based Representation

(128-dimension 1-hot vector)

#### Features

- Treat a music file as a list of notes.
- One note transitions to the next note.
- Each vector represents a note.
- Can encode notes as one hot vectors and chords as many hot vectors.

#### Disadvantages

- Cannot encode silence in music scores.
- Has no notion of duration or tempo.

### Time-Based Representation

(129-dimension many-hot vector)

#### Features

- Treat a music file as a piano roll.
- One window (e.g. size of a 16th note) is one vector.
- Each vector represents a time step.
- Encode silence by setting a 129th bit on or off.

#### Disadvantages

- Cannot encode repeated notes without silence between them.
- Size of encoding is much larger.

Figure 1. Qualitative view of generated melodies- varying structure - pink noise (t), markov chain model (m), RNN model (b)

## Model Training and Sequence Generation (Inference)

- The model outputs a probability distribution (PDF) over the notes
- For an RNN that generates a melody, we sample a single note from this PDF
- For polyphonic melodies, the model also outputs how many notes to generate. These many notes are sampled from the PDF at the time of generation

## V. Evaluation Heuristics

- Aside from a qualitative evaluation, we use a music-theory based heuristic to differentiate sequences
- The distribution of commonly used 'intervals' (note transitions) is examined

Figure 2. Pink noise shows many large jumps (octaves), best RNN (red) model has a more even distribution of 2nd, 3rd, 4th, 5th

## VI. Discussion and Future Work

- We were pleasantly surprised by the qualitatively pleasing transitions and basic patterns from our simple RNN model
- For a subjective problem, the heuristics along with qualitative analysis show how more 'pleasing' transitions and greater structure are learnt
- We are working on a modelling and sampling strategy for working with polyphonic melodies / chords
- This is difficult, since modelling the co-occurrence of notes gets exponentially harder -  $2^N$  for multi-class classification
- The note generation is also proposed to be enhanced by a beam search that explores the possibility of branching
